Amazon Alexa Based Home Automation Using Particle Photon

Shyamlal J. Shriwas¹, Dinesh V. Rojatkar²
Department of Electronics and Telecommunication, Government College of Engineering, Chandrapur, Maharashtra, India

ABSTRACT
Amazon Alexa Voice Service (AVS) is one such technologies which can helps to achieve this goal with Iot of flexibility. Particle Photon is one of IOt device in which contain microcontroller and wi-fi module interface with Amazon Alexa. In this project, a hands free Amazon Alexa voice service prototype is build on Particle photon. This project is further extended by adding skills to alexa to control or operate any appliance in home as well as in industries on our command voice.

Keywords : Amazon Echo, Alexa, automation, Internet of Things (IoT).

I. INTRODUCTION

1.1 Amazon Alexa
The idea of human machine interacting using voice led to research in Speech technology. Automatic speech recognition uses the process and related technology for converting speech signals into a sequence of words or other linguistic units by means of an algorithm implemented as a program.

Today, there are many device or software and technologies available for smart working or smart operation which has doing very easily without any hard work. Just like a Ok Google, it is already present in a smart phone; which is doing maximum task in smart phone only giving a command.

Amazon alexa is one of the smartest device among them. Amazon Alexa Echo dot is a small device which has voice-enabled wireless speaker developed by amazon lab 126. Amazon alexa is available in two model or size. This device can be connects to the voice controlled intelligent personal assistant service Alexa, which wake up or activate responds to the name "Alexa". This device is capable of voice interaction, music playback, making to-do lists, setting alarms, streaming podcasts, playing audiobooks, and providing weather, traffic and other real time information. It can also control several smart devices using itself as a home automation hub. Home automation is a very expensive luxury that a lot of people in India and other countries.

This project aims at the building a smart voice enabled device based on Alexa Voice service using Particle Photon. It demonstrates how to access and test AVS using our Java sample apps, a Node.js server, and a third-party wake word engine. Alexa voice service is Amazon's intelligent voice recognition and natural language understanding service that allows to voice enable any connect device. Alexa, the voice service provide capabilities to interact with the device in a more intuitive way. This Alexa-enabled device also provides a platform for experimenting with the current service and adding new skill to it. In the default mode the device continuously listens to all speech, monitoring for the wake word to be spoken, which is primarily set up as "Alexa". It requires a wireless internet connection in order to work. Its
The voice recognition capability is based on Amazon Web Services. Amazon Web Services (AVS) is a secure cloud service platform, offering compute power, database storage, content delivery and other functionality to help businesses scale and grow. The device performs well with a 'good' Internet connection which minimizes processing time due to minimal communication round trips, streamable responses and geo-distributed service endpoints. While the Alexa app is free, an Amazon account is required, and setup is not possible without one.

1.2 Particle Photon:

Small and power Wi-Fi connected microcontroller: Based on Cypress’s WiCed architecture, the particle photon series combines a powerful STM32 Arm Cortex M3 microcontroller and a Cypress Wi-Fi chip. This keeps to footprint small but the function board.

1.2.1 The Wi-Fi Module:

This is probably why you bought your device—the Wi-Fi module allows your Photon to communicate with the Internet in the same way that your smartphone might connect to a Wi-Fi network. Do not press down on the Photon's module. Doing so triggers a reset and is generally not good for the Photon.

1.2.2 The microcontroller:

The microcontroller is the brain of your device. It runs your software and tells your prototype what to do. Unlike your computer, it can only run one application. This application can be simple or very complex, depending on what you want to do. The microcontroller interacts with the outside world using pins.

The Particle Photon has a powerful STM M3 microcontroller as its brain and a Broadcom BCM43362 Wi-Fi chip as its connection to the internet. 18 mixed GPIO pins and a web-based IDE similar to Arduino IDE makes it easy to give connectivity to your project. The Photon has an RGB LED and two buttons—Setup and Reset—to switch between different modes to help debug your project. Particle is an open source platform, so you have access to all of their schematics and code to easily improve upon their products. Spark Fun has taken advantage and created a Photon Red Board, which gives the Photon the form factor of an Arduino so you can use your favorite Arduino shields with the Particle service.

The Photon itself is just a breakout board for their Wi-Fi module called the P0, which contains the microcontroller and Wi-Fi chip, but no antenna. The Red Board uses the P1 module, which is the P0 with a built in antenna. Both of these come preloaded with Particle firmware and access to their cloud service, but require a custom breakout board to give access to all of the pins.

Particle makes it easy to go from prototype to large scale manufacturing with these three modules. This four part series will let you know what to expect with the Photon and help you get started making your own internet of things.

II. LITERATURE SURVEY

In today’s growing world the technologies are evolving to make life easier, to make life better. One such new tech is human-machine interaction using voice. Many intelligent Voice assistants are available today:

Amazon Echo (shortened and referred to as Echo) is a smart speaker developed by Amazon.com. The device
consists of a 9.25 inch (23.5 cm) tall cylinder speaker a seven-piece microphone array. The device connects to the voice-controlled intelligent personal assistant service Alexa, which responds to the name “Alexa”. This ‘wake word’ can be changed by the user to “Amazon”, “Echo” or “Computer”. The device is capable of voice interaction, music playback, making to-do lists, setting alarms, streaming podcasts, playing audiobooks, and providing weather, traffic and other real time information. It can also control several smart devices using itself as a home automation hub.

III. METHODOLOGY

As we all know Amazon recently released Alexa Smart Home Skill API. Amazon Alexa provides built-in smart home capabilities like turning on/off lights, control air conditioners. Developer can use Alexa Smart Home Skill API to extend the smart home capabilities of Alexa. For Smart Home Skill APIs you don’t need to create a custom voice interaction models. Alexa has built-in standard interaction models for smart home, like:

*Alexa, turn on lights,*
*Alexa, set light to 50 percentage,*
*Alexa, set the temperature to 24.*

Previously Alexa works with a limited number of smart home devices like Philips Hue, etc... But with this newly introduced Smart Home Skill APIs we can integrate devices that are not supported by Alexa by default. Recently I started working on integrating Particle Device and Smart Home Skill API. I is fairly simple to create a Smart Home Skill if you already know how to create a Alexa Skill. I have created a Skill before using Particle Photon. The only issue was to figure out how to integrate OAuth2 login with Particle. Smart Home Skill API needs a server that supports OAuth2 Authorization Code Flow. With the help awesome peoples like ... I was able to integrate OAuth2 with Particle.

In this project, I emulate two lights that can be turned on/off using Alexa Voice Interaction. For the purpose of this demo, I have connected two LEDs to pins A4 and A5. Describing how to create a Smart Home Skill is not in the scope of this article. For a detailed explanation of how to create a Smart Home Skill.

In order create Smart Home Skill, Amazon requires a server that supports OAuth2 Authorisation Code Flow and Cloud APIs to control devices. At time writing this article, Amazon does not supports devices without Cloud APIs. Also as of now Alexa Smart Home Skill API supports only two types of devices, lights and air conditioners. But you can hack it to work with other type of devices also. By default the Skill you creates will be private to your account. After testing you can submit to Amazon for review and if it is approved you can make open for public. After the Skill is created, you have to enable it using the Amazon application. To enable it select Skills from side menu and find and enable your skill. Then start discovering devices using the Smart Home menu item. This will ask you to login to the cloud using the OAuth2. Once you successfully authenticated the access token will be saved and it will be passed on to your Lambda function.

When the device discovery is performed, the Smart Home Skill API will call the Lambda function attached to the Skill with Alexa. Connected Home. Discovery event. When this event is received your Lambda function will return the device list. When the user controls these devices using voice input, the Lambda function attached to the Skill will be called with Alexa. Connected Home. Control event and you can call the Cloud APIs to control the device. For a more detailed explanation of how to create Skill and Lambda function.

Some of the screenshots of the Skill Information and Lambda function is given below:

- The Particle firmware emulates two lights using LEDs. These LEDs are attached to A4 and A5 pins. The firmware has functions to turn on/off the LEDs and to set the brightness of the LEDs.
- Alexa Smart Home Skill has Skill information and the Lambda function. The Skill information contains the details about the skill such as Skill name, OAuth details, etc... The Lambda function responds to the Smart Home Skill Events.
User can interact with skill using voice input such as:

- Alexa, turn on bedroom light
- Alexa, turn off bedroom light
- Alexa, turn on kitchen light
- Alexa, turn off kitchen light
- Alexa, set kitchen light to 50 percentage.
- The Particle application is really simple, just read temperature and humidity from a DHT22 sensor. Also it has two functions to control two LEDs Red and Green. The firmware exposes three functions.
  - `gettmp` returns temperature, `gethmd` returns humidity and controls the LEDs attached to D2 and D6. On the Amazon Echo side, we have to use Alexa Skill Set to interact with it. For this I have created one Alexa Skill Set.

Following are some of the interactions possible:

User: Alexa, ask particle, what is the temperature?

Alexa: Temperature is 30 degree. Same as:

User: Alexa ask particle, what is the humidity
Alexa: Humidity is 76%.

User: Alexa, tell particle to turn on red light
Alexa: OK, red light turned on.

User: Alexa, tell particle to turn off red light
Alexa: OK, red light turned off.

User: Alexa, tell particle to turn on green light
Alexa: OK, green light turned on.

User: Alexa, tell particle to turn off green light
Alexa: OK, green light turned off.

User: Alexa, tell particle to turn on AC
Alexa: OK, AC turned on.

User: Alexa, tell particle to turn off AC
Alexa: OK, AC turned off.

Similarly we can implement any appliance in home as well as office using this Alexa based with any IoT device.

IV. CONCLUSION

Amazon echo is a voice assistant device and provide a way to communicate with it via voice and can provide different services like food delivery, request Taxi, weather, news, wikipedia, traffic, music, any smart home automation / IoT device. So it can be used almost anywhere like in home as well as office.

On focussing on technology and automation to reduce importance of the servant in home as well as in industries. Whatever any task of home, we do that task to order to amazon alexa. Just example, Alexa turn on the light, it will turn on the light; alexa book the cinema ticket at corner seat it will book the ticket, etc. This project control some home appliance in our own demand or order. This project is responsible for change the life of human being is faster, safe and luxurious.

4.1 Advantage

Amazon Alexa advantage can be found in certain categories:

1. It has a specialty to Far-field voice recognition.
2. It is able to interact Omni-direction sound.
3. Companion with Android, iOS,
4. DesktopsAlexa device has Bluetooth Enabled.
5. Echo can be extended with custom skills.

4.2 Disadvantage:

Alexa Disadvantage can be found in certain categories:

1. Sound quality - directly comparing the echo’s sound quality compared with other high quality speakers falls short, that being said the frictionless use of voice makes an improved experience.
2. Complex tasks - Alexa currently cannot process complex commands such as ‘Alexa play U2 and order me an Uber’ it lacks the ability to handle multiple commands or complex context based skills
3. Cost - There is a prohibitive cost factor of selling a $150-$180/unit

4.3 Application:

1. Asking general question to get information.
2. Making to do list for shopping purpose.
3. Play game with Alexa.
4. Playing music on mobile or controlling other mobile functions.
5. Control home appliances like light and thermostat etc.
